Cretaceous-Palaeogene event The Cretaceous–Palaeogene Event (K–T boundary) is the major boundary in the Cretaceous Period (K) and the Paleogene period (T). It separates the Cretaceous from the Palaeogene Period. The boundaries were recognized in geologic and paleontological records and are generally associated with a large shift from marine to continental environments. During the Cretaceous, the Earth experienced an abundance of volcanism and widespread sedimentary deposition. During the Paleogene, the Earth experienced a major ice age. Geological events In the early stages of the Cretaceous, the warm-to-cold climate of the Mesozoic era gradually transformed into a continent-dominated climate. The asteroid that caused the extinction of the dinosaurs 66 million years ago also caused the temporary end of the Cretaceous period. In the early stages of the Palaeogene period, the Earth was transformed into a near-glacial environment. The end-Cretaceous extinction event was caused by asteroid 65 million years ago. The impact generated a shock wave that propagated through the Earth, melting the top of the Earth's surface for about 2 million years. Sediment was distributed worldwide and marine life was wiped out. The K-T boundary is also the boundary between the Cretaceous and Paleogene Periods. It is defined as a change in the earth's climate that occurred 66 million years ago. The end of the Cretaceous and beginning of the Paleogene is when the Earth's climate cooled. The cooling was temporary and resulted in an abrupt change from a warm climate to a cooler climate. This major boundary had a global effect on climate, and can be seen in the fossil record. Paleontological significance The effects of the K–T boundary on the ecosystem
